CHEMILUMINESCENT LIGHTING ELEMENT

Devices able to emit light by the mixing of two liquid chemicals are well known. May be cited the following U.S. patents: 3 539 794, 3 576 937, 4 193 119, 4 682 544, 4 731 616, 4 814 949 and 5 121 312.

Generally speaking the proposed devices involve two chambers, respectively containing the first liquid chemical, named oxalate solution, and the second one, named activator solution. These two chambers being separated by a wall which can be broken by the user, or having a removable part. Said wall should also be a good barrier against gases, because the oxalate solution is sensitive to any contamination originating either from outside or from the activator. Therefore, in practice, save economically costly exceptions, the oxalate solution is enclosed in a breakable glass ampoule. Unfortunately, it is not possible to continuously manufacture, starting from material in roll form, elements with glass ampoules. Moreover, they are expensive.

The present invention relates to an element idoneus for such a continuous manufacture, thus very economical, and what is more, with constitutive materials being very cheap. The element has furthermore the advantage of being flat, of being particularly light, as well as other auxiliary advantages

which will appear in the following exposé.

More particularly, the invention proposes a chemiluminescent lighting element involving at least two chambers filled respectively with an oxalate solution and an activator solution. The oxalate solution is in a tight-closed pouch of thin aluminum foil, lined on its interior side by a polymer, said pouch being a first chamber. This pouch is itself enclosed in a bigger tight-closed pouch, made of translucent polymeric film, being a second chamber, which also contains the liquid activator chemical.

The element according to the invention is then essentially comprising a pouch made of aluminum foil containing the oxalate solution, disposed inside a pouch made of translucent plastic film, containing also the activator solution, and, optionally, an absorbing felt and a steel ball or other hard particle, of which the role is to pierce the aluminum pouch at the moment of use, under the effect of manipulating by the user.

The invention will be better understood with reference to the annexed drawings, shown as examples. In these drawings:

Fig. 1 represents a top plan view of the device according to the invention;

Fig. 2 is a cross-sectional view of same;

Fig. 3 is a top plan view of another embodiment of the

invention, and

Fig. 4 is its matching cross-sectional view.

The inner pouch 1 is made of the two aluminum foils 2 and 3, sealed together along their periphery 4, -rectangular in the fig. 1 and 2, and circular in the fig. 3 and 4.

It contains the oxalate liquid chemical solution, of which the level is shown as 5. The outer pouch 6 is made of two films 7 and 8, of translucent soft polymer, preferably polyolefin, for instance polyethylen or polypropylene, sealed along a periphery 9, - rectangular in the fig. 1 and 2, and circular in fig. 3 and 4. It contains the activator liquid of which the level is figured as 10.

The device involves, optionally, a steel ball 11 or a hard particle on which the user will push in order to pierce the aluminium pouch, and so induce the mixing process. It can also be conceived, that this ball or particle be not used, and that the pouch will be bursted by pressure. In that case, it is suitable to foresee an area of weakened resistance, for instance a welding line. Each of the two aluminium foils is lined, by coating, laminating, or other technique, by a coat of polymeric lacquer, on this one of their surfaces which is to be faced to the corresponding one. This lacquer coat, preferably based on a polypropylene, modified or not, is provided to ensure the adhesion of the two foils together by

1 thermal sealing along their periphery. This coat is not
2 represented on the drawings for reasons of clarity.

3 This polymeric coat, in addition to adhesion, has also
4 the role of insuring a good compatibility between aluminium
5 material and the oxalate solution which is delicate and
6 sensitive to contaminations, and is compatible with only few
7 materials. This coat is very thin, in order not to increase
8 the mechanical resistance of the aluminium, which is due to
9 become broken.

10 In addition to this coat, it is possible to also foresee
11 the presence of a thin soft film of polypropylene between the
12 two aluminium foils. It will be prisoner between them by the
13 sealing and will contribute to the quality of said sealing.
14 It is not represented on the drawings, for reasons of clarity.
15 Of course the oxalate solution will be between this soft film
16 and one of the aluminium foils, the one to be pierced.

17 The device involves also, optionally, a felt 12
18 (succession of small crosses on the drawings) made of nonwoven
19 material of which the fibers are preferably from the same
20 polymer as the films of the outer pouch. It will be prisoner
21 between the two films by the peripheral thermal sealing.
22 During the storage of the lighting element before use, this
23 felt will have time to absorb the whole of the activator
24 liquid and spread it uniformly in the pouch. The result will

1 be a good uniformity in emitted light after the liberation of
2 the oxalate solution, because the two chemical liquids are
3 said to diffuse into each other within a short time. The
4 level of activator liquid as figured in 10 in fig. 2, is the
5 one met at the time of filing; later, it will be absorbed in
6 the felt as said above.

7 Once emptied, or almost emptied, the aluminium pouch
8 remains in place and has a role of reflector; the whole of
9 luminous emission takes place indeed from the same side of the
10 aluminium pouch, -the pierced side. There is almost no liquid
11 at the other side. This intense unidirectional emission of
12 light is incontestably an advantage towards prior art in the
13 matter.

14 It is frequent that the inner pouch be not entirely
15 emptied by the user at the time of lighting-up. It has been
16 seen that some rests were remaining inside because of some
17 creases or other reasons. It is then advantageous, while the
18 light is weakening with the hours, due to the unavoidable
19 chemical energy consumption of the system, to handle the
20 element with some kneading action, in order to extract the
21 remains of oxalate solution contents out of the inner pouch.
22 One can then see a kind of regeneration of the luminous
23 emission, and this, at the moment decided by the user. This
24 is an appreciable advantage versus the prior art, vainly asked

1 for, until now, by the market.

2 In fig. 1 and 2 the element is figured under a rectangle
3 form, and in fig. 3 and 4, under a circular form, but of
4 course the peripheral sealing can have any other form, and,
5 particularly, for advertising or promotional purposes, be made
6 under the form of a brand logo.

7 For industrial manufacture, it is foreseen, with use of a
8 "fill-and-seal" type of packaging machine, to unroll, from
9 their respective storage rolls, the two aluminium foils, as
10 well, if any, the optional roll of soft polymer film, in order
11 to present face to face the coated sides of these aluminium
12 foils, and to seal successively the pouches in a continuous
13 and temporized way.

14 When the aluminium foils are face to face, one of them-
15 or both- is slightly embossed by a small punching tool,
16 mechanically actuated, this in view of creating some volume
17 for the liquid to be received. Then the injection of oxalate
18 solution is done, followed by the pouch sealing. Once sealed,
19 the pouches are separated by means of an automated knife, and
20 fall individually into the second machine, described
21 hereafter.

22 The machine can be of vertical type, as suggested by fig.
23 1 and 2, or of horizontal type, as suggested by fig. 3 and 4.
24 The embossing operation is easier in horizontal machine and

can be done in the inferior foil only.

The aluminium foils have been coated or laminated with the polymeric lacquer mentioned hereabove, in the course of a previous operation, which has also be done continuously by known means.

A second machine, also of the "fill-and-seal" type, receives in a sequential way, synchronously with the first machine, the filled and sealed aluminium pouches, and seals together the two soft plastic films, as well as the felt if any, all three of them being continuously unrolled from their storage rolls. Before sealing, a measured quantity of activator liquid is introduced, as well as the ball.

It is important to note that in this second machine, which manufactures the outer pouches (and this, contrarily to what happens in the first machine with the aluminum foils) the two films of flexible plastic, unrolled in view of the operation, remain flat, i.e. not "embossed" or "deepdrawn" until the moment of final sealing. They then take a slightly swollen structure because at the sealing time, they cage between them the aluminium pouch. This swelling is a purely elastic deformation, with tensioning, due to the natural elasticity of the films, by nature reversible. As a result the walls of the outer pouch exert on the inner pouch and its contents, a uniform elastic pressure of which the action is

1 very favorable at the moment of piercing by the user. The
2 exalate liquid is then ejected with force, what favours the
3 desired mixing.

4 The completed pouches then go out from the exit of the
5 machine under the form of a chain, or sausage chain, and can
6 be supplied as such to the user, if he is interested by light
7 "in-line", -a novel item being of interest for instance for
8 police or army forces.

9 Of course the pouches can be separated from each other by
10 means of an automated knife, or by weakened lines- precut
11 lines- for ulterior separation by the user himself.

12 Examples of embodiments.

13 Example 1.

14 In this example, it is made use of a vertical machine, of
15 modified "fill-and-seal" type. The used aluminium foil is of
16 Reynolds brand, in tape of 35 mm width, and 300 metre long
17 rolls. Thickness is 28 micrometres for the face to be pierced
18 and 38 micrometres for the other one.

19 Before being slit into rolls of 35 mm width, said foil
20 has been coated on its full width -600 mm- with polypropylene
21 dispersion, and cured in a tunnel oven. The remaining
22 deposited thickness after cure is 6 micrometre.

23 When the two aluminium foils are face to face, their
24 mutual sealing is done along a rectangular periphery of 33 x

1 off or except on the upper side, through which an embossing
2 finger mechanically penetrates accompanied with a needle for
3 injection of the oxalate solution, then these two elements
4 withdraw, and the sealing is completed.

5 The oxalate solution consists of a dibutylphthalate
6 solvent in which, per litre, are dissolved 120 grams of CPP
7 oxalate and 1.5 gram of DPEA dye. These components are well-
8 known in the prior art in matter of chemiluminescent elements.

9 The ball is a bearing ball, of third choice, diameter 4.5
10 mm.

11 The films in the outer pouch are of copolymer
12 polypropylene-polyethylene without slip-agent in the formula,
13 thickness 0.25 mm, in rolls of 40 mm width, 300 m length.

14 The measured quantities of oxalate solution and activator
15 solution are respectively 1.7 and 0.7 millilitre.

16 Sealings are done by jaws or anvils having the shape of
17 rectangles with rounded corners, with an effective sealing
18 width of 2 mm. The thermal energy for the sealings is brought
19 either by electrical resistances or via an ultrasonic
20 generator.

21 The felt is a nonwoven "spunbond" film of polypropylene
22 and polyethylene fibers, of 120 grams per square metre.

23 The completed items, separated by a automatic temperized
24 knife, have a dimension of 45 x 70 mm and a weight of 4 grams.

1 Example 2.

2 The process is same as in Example 1, but with use of an
3 horizontal type machine. The embossing of the lower aluminium
4 foil is done by lowering a punching tool prior to any sealing;
5 then the depositing of the liquid chemical is done with a
6 removable needle, thus the sealing between the two aluminium
7 foils is done in one shot along the whole periphery.

8 In this case the aluminium tapes feeding the machine have
9 a width of 41 mm, and those of flexible plastic film, a width
10 of 65 mm. Quantities of oxalate solution and activator
11 solution are respectively 2.2 and 1.1 millilitre. Completed
12 items have a diameter of 59 mm and a weight of 5 grams.
